Battery cabinet balancing current

Overview

The role of the BMS balancing current is to equalize the State of Charge (SoC) of individual cells within a battery pack. By achieving this balance, all cells reach the same SoC during the charging and discharging cycles.

The role of the BMS balancing current is to equalize the State of Charge (SoC) of individual cells within a battery pack. By achieving this balance, all cells reach the same SoC during the charging and discharging cycles.

The BMS serves as an intelligent electronic system responsible for monitoring and managing various aspects of a rechargeable battery, including voltage levels, current flow, temperature, and State of Charge (SoC). Among its essential functions, balancing battery cells emerges as a crucial task. The

Redistribution allows use of all the energy in the battery; it requires significantly higher currents than balancing. The point of balancing is to maximize the charge that the battery can deliver, limited only by the cell with the lowest capacity. A balanced battery is one in which, at some State.

Different algorithms of cell balancing are often discussed when multiple serial cells are used in a battery pack for particular device. The means used to perform cell balancing typically include by-passing some of the cells during charge (and sometimes during discharge) by connecting external loads.
